

OCCULTATIONS OF PLANETS AND BRIGHT STARS BY THE MOON

October 28, 2017

The moon, as our nearest neighbor, sometimes blocks the light coming from a planet, a star, or the sun. Occultations are listed below for the years 2017-2021. The name of the planet or star, along with its visual magnitude, is listed along with the percentage of the moon's disk that is illuminated at the time, and the phase of the moon. The date and time (UTC) when the geocentric angle between the center of the moon and the center of the planet or star is minimal (mid-point of the occultation), and the angle of separation are the next items listed.

For local times, subtract 7 hours from UTC to obtain MST, or 6 hours for MDT.

The date and times when the occultation first commences, and last ends, for the first and last observations on earth are listed, followed by the latitude and longitude of the location where the line from the object's center through the moon's center strikes the surface of the earth at mid-occultation.

If the occultation is visible, in whole or in part, from the **Hidden Valley Observatory**, the times (UTC) of the various stages are listed along with the altitude above the horizon of the moon, the object, and the sun respectively. For occultations, when the moon is above the horizon, but not the sun, this is noted with three asterisks (***) . If, on the other hand, the Moon is visible at HVO when the object in question is closest to the Moon, but the planet or star is not occulted because of perspective, then the angle between the edge of the Moon and the edge of the object is listed.

Note: the data listed below depend on estimates of DUT1 and DUTC. Also, a number of other factors are involved in the computation of an occultation, and the results given here can easily be off by a few seconds. In addition, direct visual observation can be uncertain in terms of reaction time, and in establishing the accuracy of the clock you use.
